

A Censoring model: predictors of complete follow-up

Note: SE not archived; error bars omitted. Positive beta = predictor associated with higher probability of observed outcome.

B Performance: complete-case vs IPCW-weighted (labels = difference)

Among 9,207 FI-eligible CLHLS participants aged ≥ 60 , 2,112 (22.9%) had a missing four-year outcome. Panel A: logistic model for the probability of complete follow-up (censoring is mildly informative, so MCAR does not hold). Censoring by FI tertile: 25.2% (low), 24.1% (middle), 19.6% (high). Panel B: inverse-probability-of-censoring weights (mean 1.29, max 1.45 after 99th-percentile truncation) changed every metric negligibly (C-index +0.0008).
